NOTES 10: SAMPLING DISTRIBUTIONS

Stat 120 | Fall 2025 Prof Amanda Luby

"Big picture" picture:

Quantity Statistic Parameter

Mean
Proportion
Standard Deviation
Correlation
Regression Coefficient

Carleton publishes an "at a glance" page with some facts and figures about the student body: https://www.carleton.edu/about/carleton-at-a-glance/

Some highlights:

- Geographic distribution:
 - Midwest 36.7%
 - West 21.7%
 - East 17.3%
 - South 10.9%
 - International 11.8%
 - Other 1.6%
- 34% BIPOC
- 12% are among the first generation in their families to attend college
- 61% graduated in the top 10% of their high school class

In a moment, we're going to see one of these quantities for our class. Before we do, what is your best guess for each of these quantities?

Example: In this set-up, what is the:

- Population
- Sample
- Parameter

Statistic

We know that our class will likely not have exactly 36.7% from the Midwest, but we probably wouldn't expect it to be 0% or 90%.

```
Sampling variability
```

We might start to ask ourselves, what if a different set of 32 students enrolled in this course?

First, we create a population.

```
# A tibble: 2,007 x 2
   student_id midwest
        <int> <chr>
 1
          193 Yes
 2
         1062 No
 3
          111 Yes
 4
         1111 No
 5
          533 Yes
 6
         1686 No
 7
         1776 No
 8
         1224 No
9
          877 No
10
          338 Yes
# i 1,997 more rows
```

Then, we take a random sample:

```
set.seed(100424)
sample1 <- carls |>
    sample_n(32)
sample1
```

```
# A tibble: 32 x 2
   student_id midwest
        <int> <chr>
 1
         1259 No
 2
          826 No
 3
          858 No
 4
         1905 No
 5
           40 Yes
 6
         1336 No
 7
         1607 No
         1757 No
```

```
9 489 Yes
10 445 Yes
# i 22 more rows
```

and calculate the proportion of "yes" responses:

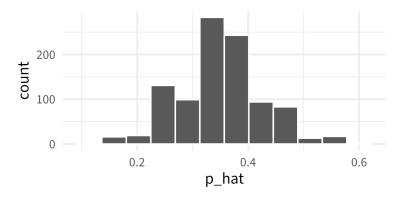

```
sample1 |>
  group_by(midwest) |>
  summarize(
   n = n()
) |>
  mutate(p_hat = n/sum(n))
```

This isn't super useful, but if we do it a bunch of times, we can start to see what a range of possible samples could look like. (Note: this code requires the {infer} package)

```
many_samples <- carls |>
  rep_sample_n(35, reps = 1000, replace = TRUE) |>
  group_by(replicate, midwest) |>
  summarize(
    n = n()
    ) |>
  mutate(p_hat = n/sum(n)) |>
  filter(midwest == "Yes")
many_samples
```

```
# A tibble: 1,000 x 4
# Groups: replicate [1,000]
   replicate midwest
                         n p_hat
       <int> <chr>
                    <int> <dbl>
1
           1 Yes
                       12 0.343
 2
           2 Yes
                        8 0.229
 3
           3 Yes
                       15 0.429
 4
           4 Yes
                        16 0.457
 5
           5 Yes
                       15 0.429
 6
           6 Yes
                        16 0.457
 7
           7 Yes
                       16 0.457
 8
           8 Yes
                       17 0.486
9
           9 Yes
                       15 0.429
```

Looking at this first few rows, we can start to get a sense of the range of possible sample proportions, but there are 990 rows that we can't see. Let's make a graph!

Example: Carleton Mission Statement

In your own words: provide explanations for:

Population distribution

Sample distribution

Sampling distribution
