# **NOTES 10: SAMPLING DISTRIBUTIONS**

Stat 120 | Fall 2025 Prof Amanda Luby

"Big picture" picture:

Quantity Statistic Parameter

Mean
Proportion
Standard Deviation
Correlation
Regression Coefficient

Carleton publishes an "at a glance" page with some facts and figures about the student body: https://www.carleton.edu/about/carleton-at-a-glance/

### Some highlights:

- Geographic distribution:
  - Midwest 36.7%
  - West 21.7%
  - East 17.3%
  - South 10.9%
  - International 11.8%
  - Other 1.6%
- 34% BIPOC
- 12% are among the first generation in their families to attend college
- 61% graduated in the top 10% of their high school class

In a moment, we're going to see one of these quantities for our class. Before we do, what is your *best guess* for each of these quantities?

### **Example:** In this set-up, what is the:

- Population
- Sample
- Parameter

#### Statistic

We know that our class will likely not have **exactly** 36.7% from the Midwest, but we probably wouldn't expect it to be 0% or 90%.

```
i Note
Sampling variability
```

We might start to ask ourselves, what if a *different* set of 32 students enrolled in this course? First, we create a population.

```
# A tibble: 2,007 x 2
   student_id midwest
        <int> <chr>
 1
          193 Yes
 2
         1062 No
 3
          111 Yes
 4
         1111 No
 5
         533 Yes
 6
         1686 No
 7
         1776 No
 8
         1224 No
9
          877 No
10
          338 Yes
# i 1,997 more rows
```

Then, we take a random sample:

```
set.seed(100424)
sample1 <- carls |>
    sample_n(32)
sample1
```

```
# A tibble: 32 x 2
   student_id midwest
        <int> <chr>
         1259 No
1
 2
          826 No
 3
          858 No
 4
         1905 No
 5
           40 Yes
 6
         1336 No
 7
         1607 No
```

```
8 1757 No
9 489 Yes
10 445 Yes
# i 22 more rows
```

and calculate the proportion of "yes" responses:

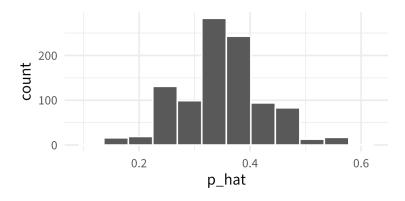

This isn't *super* useful, but if we do it a bunch of times, we can start to see what a range of possible samples could look like. (*Note:* this code requires the {infer} package)

```
many_samples <- carls |>
  rep_sample_n(35, reps = 1000, replace = TRUE) |>
  group_by(replicate, midwest) |>
  summarize(
    n = n()
  ) |>
  mutate(p_hat = n/sum(n)) |>
  filter(midwest == "Yes")
many_samples
```

```
# A tibble: 1,000 x 4
# Groups:
           replicate [1,000]
                        n p_hat
   replicate midwest
      <int> <chr> <int> <dbl>
                      12 0.343
1
          1 Yes
 2
                        8 0.229
           2 Yes
 3
          3 Yes
                       15 0.429
 4
          4 Yes
                       16 0.457
 5
                       15 0.429
          5 Yes
 6
          6 Yes
                       16 0.457
 7
          7 Yes
                       16 0.457
 8
          8 Yes
                       17 0.486
```

9 9 Yes 15 0.429 10 10 Yes 10 0.286 # i 990 more rows

Looking at this first few rows, we can start to get a sense of the range of possible sample proportions, but there are 990 rows that we can't see. Let's make a graph!

**Example:** Carleton Mission Statement

*In your own words:* provide explanations for:
